Ideas/Suggestions/To Do

See US-chartbook project on GitHub for source code and list of issues.

Continue to fill out the content of the document. Additionally, refactor some of the older code and clean up some of the issues with older charts and text. Data retrieved from Census, BLS, the Fed and others needs to be stored in the SQL database, the way BEA data is stored. Individual notebooks or python files should be created for each source.

A lot of editing is needed, as the current text is full or errors and often not ideal. Some of the text is already good, but much of it is still in early drafts or not available at all. Part of speeding up the text generation, and cleaning up the existing code, will be writing a module that generates several options for a text value.

Shift approach slightly towards making document more accessible to audience without econ background. The primary way to do this is to offer three types of intuition: mathematical, graphical, and logical. In addition to this, try to present data in text, charts, and tables.

Critical to emphasize the importance of multiple approaches to GDP compilation. Many people in the US think about GDP only from the expenditure approach, but the income approach is equally important, and arguably more intuitive.

Section listing recent updates and upcoming releases would be nice. This would require some thinking in terms of implementation.

Get the table of contents up and running soon. Also look into options for links to footnotes at the end of the document. Add in some table and release numbers/data where available.

Beyond content, I still need to do/add: links to sources, links to code, date of last update, list of charts and numbering system, links between charts and references, marks for recent updates, explicitly note seasonal adjustment, adjusting to make text associated with values of less than one singular instead of plural (e.g. "0.1 percentage point"), and much much more.

In many cases, a link to a .csv file contained the data used in the chart  is available in the bottom right corner of the chart. Each page also has a link to the table of contents in the bottom right corner of the page, to the right of the page number.

Major LT developments: rise of imports, computers in the 1990s, welfare reform in 1996, rise in education level, aging of the population. Major MT developments: increase in health care costs, housing bubble, government austerity from 2010 to 2014. Major ST developments: low business investment, higher wages, increased employment, low interest rates on LT debt, low productivity growth.

Overview

The US Chartbook aims to be comprehensive, but not arbitrary, in presenting charts, tables, and analysis. The results are fairly detailed, but hopefully well-curated and well-organized.

This first section discusses high-level indicators of the health of the US economy. Subsequent sections offer more detail on types of activity, sectors, and markets. Finally, some international comparisons are presented.

This first page should show the horizontal range chart for the top five indicators: GDP growth, wages, epop, cpi inflation, and 10 year treasury yields. Additional information on each one should be pretty brief, but the section should be heavy on links to other, more detailed, sections.

Perhaps also provide some high level context in this section, by converting large numbers into small ones.

Overall Economic Activity

This analysis of the United States economy begins with the most popular measure of economic activity, Gross Domestic Product (GDP). According to the Bureau of Economic Analysis, GDP–the seasonally-adjusted annualized value of goods and services produced in the US–was $21,542 billion in the third quarter of 2019, compared to an inflation-adjusted equivalent of $10,254 billion in the first quarter of 1989.

The US population is growing by about sixth-tenths of a percent per year. GDP per capita (see —), adjusted for inflation to 2019 Q3 dollars, has increased to $65,342 in 2019 Q3 from $41,605 in 1989 Q1.

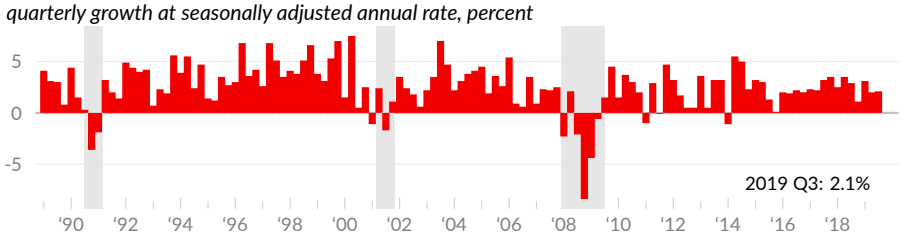
GDP per capita
in 2019 Q3 dollars

Source: Bureau of Economic Analysis

Economic Growth

GDP (see ■) increased at an annual rate of 2.1 percent during the third quarter of 2019, compared to an increase of 2.0 percent in the second quarter of 2019. Quarterly growth has averaged 2.5 percent over the past three years, 2.3 percent over the past 10 years, and 2.5 percent over the past 30 years.

Real Gross Domestic Product Growth
quarterly growth at seasonally adjusted annual rate, percent

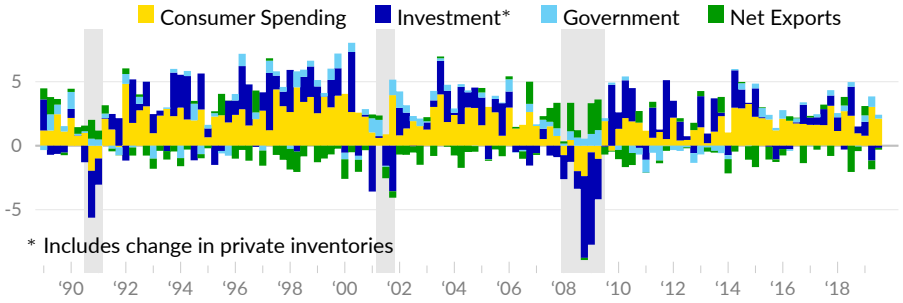


Source: Bureau of Economic Analysis

Components of Growth

The **expenditure approach** compiles GDP from the sum of spending on domestic goods and services. Major spending categories are consumer spending (see ■), private investment (gross spending on capital goods) and changes in private inventories (see ■), government spending and investment (see ■), and net exports (see ■) which is measured as foreign spending on US goods and services less US spending on goods and services produced by the rest of the world.

Real GDP Growth by Expenditure Type
percentage point contribution to GDP growth

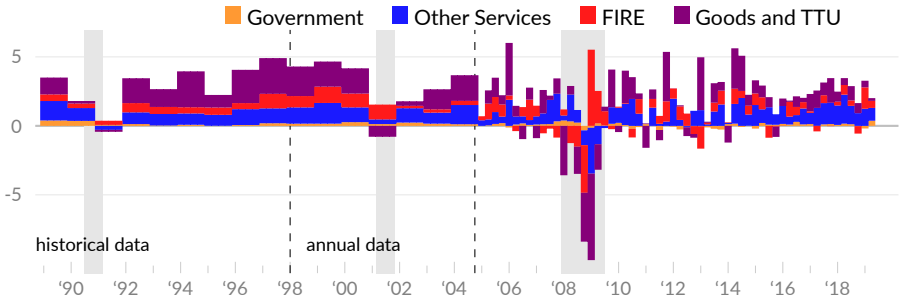


Source: Bureau of Economic Analysis

The **production approach** calculates GDP as the sum of gross value added–output minus inputs–in each sector. This identifies contributions from: goods-producing sectors combined with trade, transportation, and utilities (see), finance, insurance, and real estate (see), other service-providing sectors (see), and government (see).

Real GDP Growth by Industry Group

percentage point contribution to GDP growth

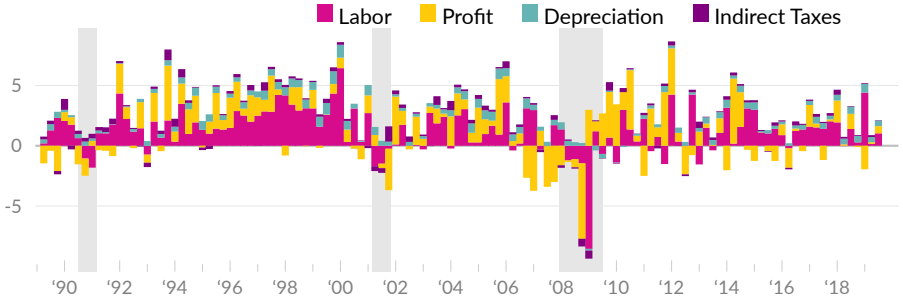


Source: Bureau of Economic Analysis

The **income approach** calculates GDP as the sum of market income to persons (in exchange for labor (see) or from returns on capital (see)), indirect taxes such as sales taxes or tariffs (see), and depreciation (see).

Real Gross Domestic Income Growth

percentage point contribution to GDI growth



Source: Bureau of Economic Analysis

Changes to GDP can be assigned to changes in **household inputs**: population (see), employment rates (see), average hours worked (see), and total economy productivity (see).

Financial Accounts

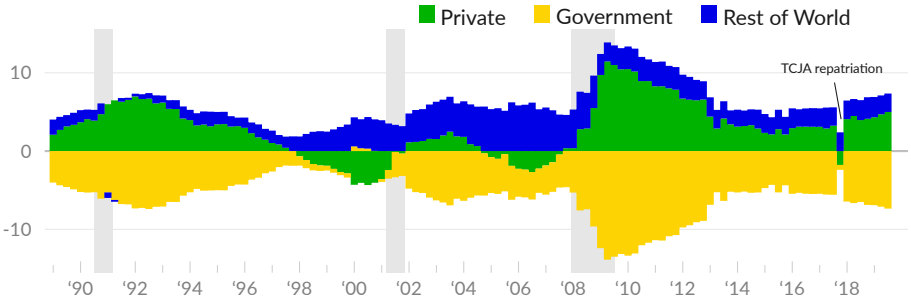
The Federal Reserve reports the balances and transactions in the US financial accounts. This includes the flow of funds between sectors in the economy and the various components of balance sheets by sector, such as for households, businesses, and government. The sector-specific data are covered in the section of the chartbook that corresponds to the sector, however, the overall financial activities of the US are discussed in this section.

Sectoral Balances

A high-level overview of US financial activities can be provided by dividing the world economy into three sectors: the US private sector (see ■), the US government (see ■), and the rest of the world (see ■), then examining the net lending and borrowing between the groups, which must sum to zero at an aggregate level. That is, if one sector is running a deficit, another sector must be running a surplus.

Sectoral Financial Balance

net lending (+) or borrowing (-), NIPA basis, by sector, as share of GDP



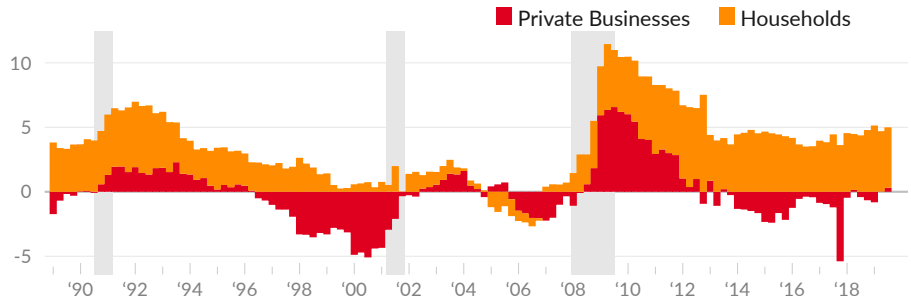
Source: Bureau of Economic Analysis

In 2019 Q3, the US private sector was a net lender (running a surplus) of the equivalent of 5.0 percent of GDP, compared to 2.3 percent in 2015 Q1. The rest of the world was a net lender to the US, to the equivalent of 2.4 percent of GDP in 2019 Q3 compared to 2.4 percent in 2015 Q1. Balancing these transactions, the government (federal, state, and local combined) was a net borrower (running a deficit) of the equivalent of 7.4 percent of GDP, compared to 4.7 percent in 2015.

Within the private sector, households were net lenders of the equivalent of 4.7 percent of GDP in 2019 Q3, while the net financial balance of private businesses–corporate and noncorporate–was 0.3 percent of GDP.

Domestic Private Sector Financial Balance

net lending (+) or borrowing (-), NIPA basis, by sector, as share of GDP



Source: Bureau of Economic Analysis

Liabilities

The contribution of different sectors to the total change in borrowing can identify potential risks in the domestic economy. For example, the tech bubble of the late 1990s and early 2000s shows up as a large increase in corporate borrowing. The housing bubble from the 1990s to 2007 shows up as an increase in household borrowing. Government borrowing increased following the collapse of the housing bubble, in an effort to compensate for the massive fall in wage income. Keep in mind, however, that the vast majority of liabilities in the domestic economy are to other domestic parties.

Domestic liabilities increased by 3.8 percent over the year ending 2019 Q3, after adjusting for inflation. Over the past three years, total domestic liabilities increased at an average annual rate of 3.0 percent. The federal government contributed 0.8 percentage points per year on average (see ■), while the state and local government subtracted 0.1 percentage points per year on average (see ■). Households and nonprofits contributed 0.3 percentage points per year on average over this three year period (see ■), corporate businesses contributed 1.5 percentage points per year on average (see ■)and non-corporate businesses contributed 0.5 percentage points per year on average (see ■).

Real Debt Growth

contribution to one-year percent change in liabilities, adjusted by PCE price deflator

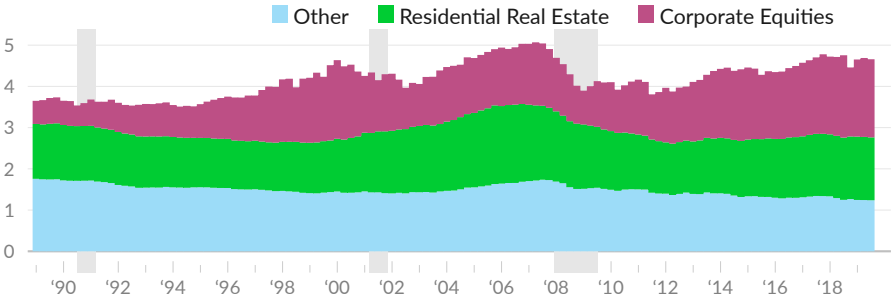
[TABLE HERE]

Wealth

Total US wealth is the tangible assets of all non-corporate sectors of the US, plus the market value of domestic corporate equities, less US financial obligations to the rest of the world. The ratio of US total wealth, excluding public lands, to GDP increased to 4.66 in 2019 Q3 from 3.65 in 1989 Q1. The market value of corporate equities (see ■) increased to a 1.89 multiple of GDP in 2019 Q3 from 0.56 in 1989 Q1. The market value of residential real estate (see ■) increased to 1.53 times GDP from 1.33 in 1989. The other category (see ■), which includes tangible assets other than residential real estate less US financial obligations to the rest of the world, decreased to 1.24 from 1.76 in 1989.

Total US Wealth to GDP Ratio

total US wealth divided by GDP



Source: Federal Reserve

Additional text here. Also need more explanation above for other category because it is so large. Could also consider showing obligations to ROW as a category, but that only makes ”other” larger, which means even more need for explanation. A table or bar chart that provides more detail could also do the trick.

Within categories of wealth, the ratio of corporate equities to other categories of wealth has increased considerably...

[BAR CHART - WEALTH / GDP BY TYPE]

Investment

Private fixed investment, as measured in the national accounts, includes construction and improvement of houses, apartment buildings, and other residential property (see ■), but not automobiles, appliances, or furniture. Non-residential private fixed investment includes the construction and improvement of offices, warehouses, factories, and other commercial and industrial property (see ■), as well as purchases of equipment and intellectual property products. The change in private inventories (see ■) at the end of the accounting period is also, at times, grouped with investment.

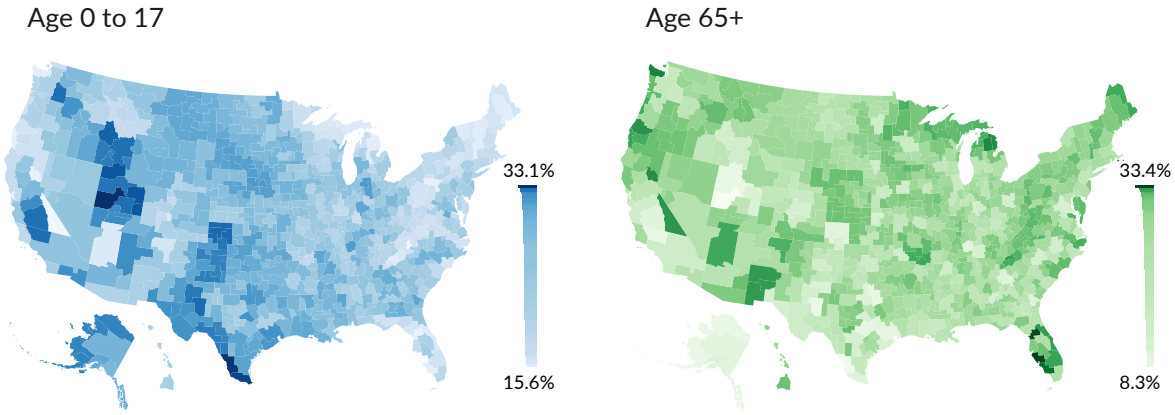
[TABLE HERE WITH SECTOR INVESTMENT OVERVIEW]

Households

This section covers the household sector of the economy loosely defined, and touches on demographics, personal income and outlays, residential fixed investment, household balance sheets, home ownership, housing prices, and housing construction and permitting.

[Table or chart on population]

Age Group Share of Commuter Zone Population, 2018



Source: American Community Survey, Dorn

Demographics and Household Formation

The Census Bureau estimates that the US population is 327.2 million in 2018 and reports population growth of 0.6 percent over the past year. By age, 22.9 percent are under the age of 18 and 16.1 percent age 65 or older. In 1989, the US population was 246.8 million, with 25.7 percent under 18 and 12.4 percent 65 or older.

This section should capture 1) population, 2) population growth, 3) aging, 4) increased education.

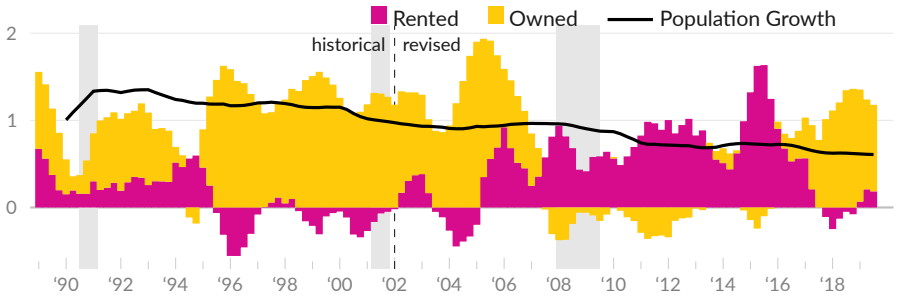
Household Formation

Household formation, measured here as the one-year change in total occupied housing units, can result from a net increase in renters or a net increase in homeowners. Household formation should keep pace with population growth, all else equal. During the housing bubble, the home-ownership rate increased and household formation exceeded population growth. Following the collapse of the housing bubble, housing formation was often below population growth. Additionally, home ownership decreased as foreclosures converted homeowners into renters.

As of 2019 Q3, there are 122.7 million total occupied housing units in the US, of which 43.2 million (35.2 percent) are rented, and 79.5 million (64.8 percent) are owner-occupied. There was an average annual net total increase of 1.4 million housing units over the year ending 2019 Q3, the result of 224 thousand net new renter households and 1.2 million net new owner-occupied households. Over the year ending 2019 Q3, the total number of occupied housing units increased by 1.2 percent, compared to an increase of 1.2 percent percent in 2019 Q2. Owner-occupied units contributed 1.0 percent to total household formation on average over the year (see), compared to a a contribution of 0.2 percent from rented units (see).

Household Formation by Type

one-year moving average of annual growth rates



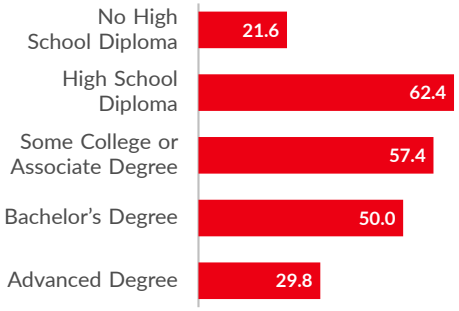
Source: Census Bureau, Housing Vacancies and Homeownership

Education

Education is central in many discussions of the future of the US economy. Though very expensive in forgone years of earnings and often also expensive in tuition and textbooks costs, education typically results in higher earnings. In response to changing job opportunities from globalization and other policy decisions, household spending on education has increased considerably, resulting in a much more educated population.

Over the year ending November 2019, 79.8 million people over the age of 25, or 36.1 percent of the total, have at least a bachelor's degree, with 29.8 million of those, or 13.5 percent of the total, holding an advanced degree such as a master's degree, medical or law degree, or PhD. An additional 57.4 million people have some college coursework but no degree or have an associate degree. A total of 62.4 million have a high school diploma but no college, while 21.6 million have no high school diploma.

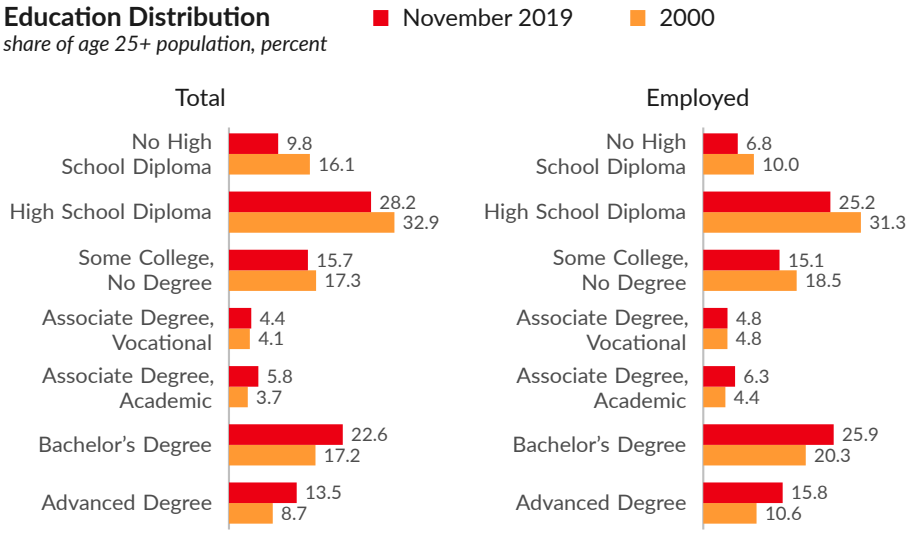
Highest Level of Education
age 25+ population, in millions, November 2019



Source: Author's Calculations from CPS

The share of the population with a bachelor's degree or advanced degree increased by 10.2 percentage points since 2000. The increase is even more pronounced among those who are employed; 41.7 percent have a college degree or advanced degree in November 2019, an increase of 10.7 percentage points since 2000. One argument is that households were compensating for a weak labor market and lack of bargaining power by borrowing large sums of money for education. However, given the extent of the increase in education, and the typical wage premium of education, labor income should have increased much more than it actually did.

Education Distribution
share of age 25+ population, percent



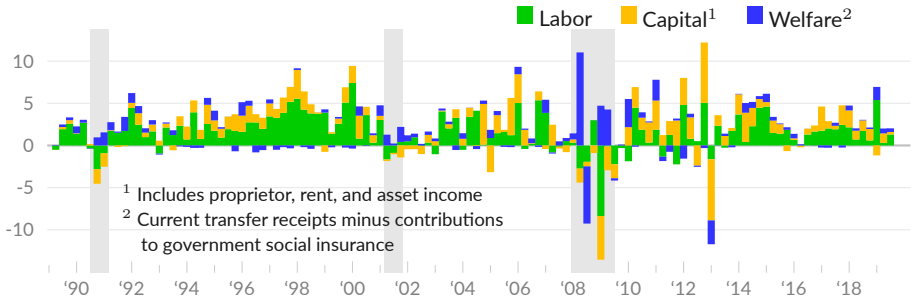
Source: Author's Calculations from CPS

Income to Persons

This section looks at income received by people, by type of income, adjusted for inflation using the PCE implicit price deflator. Income is divided into labor income (see ■), which is measured as compensation of employees, capital income (see ■), measured as the sum of proprietor income, rental income, and dividend and interest income, and welfare income (see ■), which is measured as transfers to persons less contributions to social insurance.

Personal Income

percentage point contribution to real personal income growth



Source: Bureau of Economic Analysis

Aggregate real personal income increased at an annualized rate of 2.03 percent in 2019 Q3. Labor income contributed 1.30 percentage points to overall growth, capital income contributed 0.30 percentage points, and welfare income contributed 0.43 percentage points.

Earnings, which include wages and salaries as well as self-employment income, comprise the majority of personal income. Yet only 52 percent of people have any earnings in 2018. Only 43 percent of people have earnings above the single-person poverty threshold.

Total income, including taxes, welfare, and capital income, reaches 71 percent of people. The remainder live with people with income or receive private transfers.

Capital Income

Welfare Income

[**Breakout section on income of the aged**]

Income of the aged is looking like a very important section. I hadn't realized the extent to which demographics are rapidly putting downward pressure on the employment rate. Something like four percent of the population is shifting from work age to retirement age.

It's important here to point out that social security retirement income is the solution, not the problem. There has been a reduction in private retirement benefits in the form of defined benefit pension plans and a shift towards reliance on 401k and IRA plans. But social security has never missed a payment. In contrast, hundreds of thousands of people are pushed in bankruptcy each year by medical bills. By not extending social insurance to younger people, a larger portion of pre-retirement-age people have their savings wiped out by common life events like having children or a period of illness. As a result, more pressure is put on social insurance for retirement.

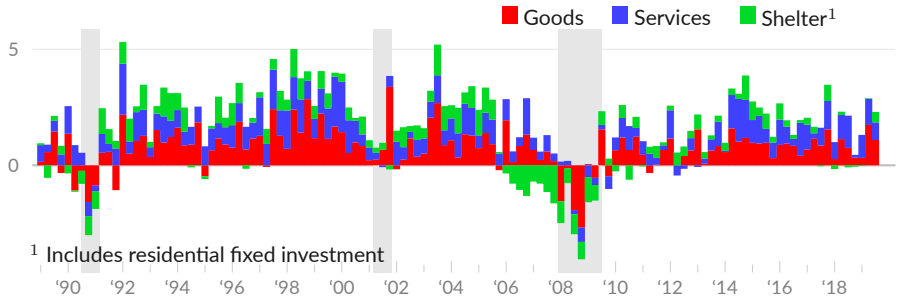
Ideally I would like to look at the demographics (employment adjustment for age), and then replicate the income of the aged calculation on an annual basis to show how many households are kept out of poverty by social security retirement income.

Household Expenditures

This section covers household spending on goods (see ■), services excluding housing and utilities (see ■), and shelter (see ■ , calculated as housing services and utilities combined with residential fixed investment). These categories contributed 2.14 percentage points to GDP growth in 2019 Q3 compared to an average contribution of 1.85 percentage points over the past three years.

Consumer Spending and Residential Investment

percentage point contribution to GDP growth



Source: Bureau of Economic Analysis

In the third quarter of 2019, household spending on goods contributed 1.09 percentage points to GDP growth, household spending on services other than housing and utilities contributed 0.76 percentage points, and shelter spending and investment contributed 0.45 percentage points. Spending on health care services contributed 0.07 percentage points to GDP growth in 2019 Q3 and has contributed 0.28 percentage points, on average, over the past three years.

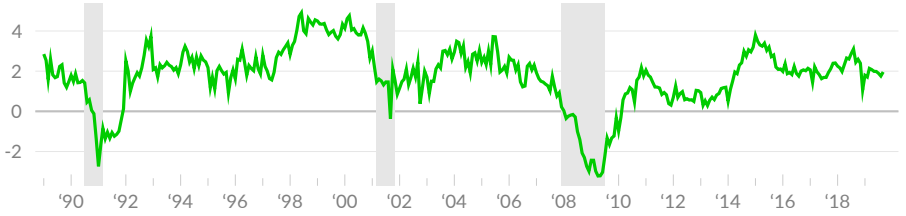
Consumer spending is also reported on a monthly basis. Inflation- and population-adjusted consumer spending increased by 2.0 percent over the year ending September 2019, compared to an increase of 2.4 percent over the year ending September 2018.

Consumer Spending Growth

annual growth, per capita real personal consumption expenditures, percent



Source: Bureau of Economic Analysis

[Top quintile consumer spending share of gross pre-tax income and bottom 80 percent share]

Income and Expenses by Age and Number of Children

Changes to consumer spending (see —) are largely the result of changes to income (see ■) and changes to the rate at which income is saved (see ■). Changes to other outlays (see ■) reflect changes in interest payments, fines and fees, and charitable giving.

Real per capita consumer spending increased at an average rate of 1.9 percent over the four quarters ending 2019 Q3. Changes to disposable income added 2.6 percentage points, changes to saving subtracted 0.6 percentage points, and changes to other outlays didn't affect the total. Over the past three years, real per capita consumer spending growth has averaged 2.2 percent, with income growth contribuing an average of 3.1 percentage points and saving subtracting an average of 0.7 percentage points.

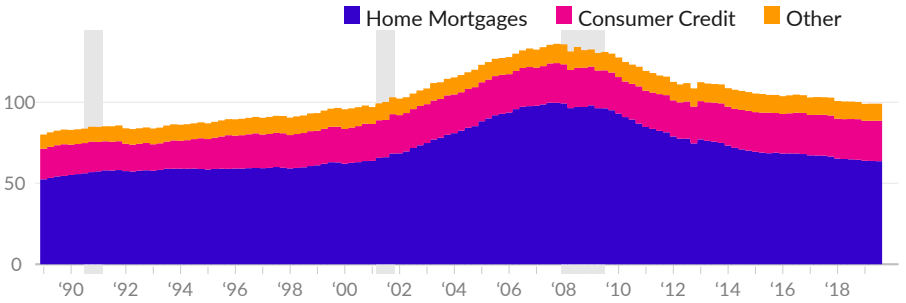
Household Balance Sheets

Liabilities

The Federal Reserve reports total liabilities of households and nonprofits of $16.39 trillion in 2019 Q3. The vast majority–$10.52 trillion or 64.2 percent of the total–are home mortgages (see ■). Consumer credit liabilities (see ■) which include auto loans, credit card debt, student loans, and other personal loans, total $4.13 trillion (25.2% of the total). The remaining liabilities (see ■) are primarily attributable to nonprofits.

The ratio of household and nonprofit debt to disposable personal income has fallen to 99.1 percent in 2019 Q3 from its housing-bubble peak of 136.1 percent in 2007 Q4. Over the past three years, nominal household and nonprofit debt has increased 10.2 percent while nominal disposable personal income has increased 16.4 percent. As a result, the ratio of household and nonprofit debt to disposable personal income has fallen by 5.6 percentage points.

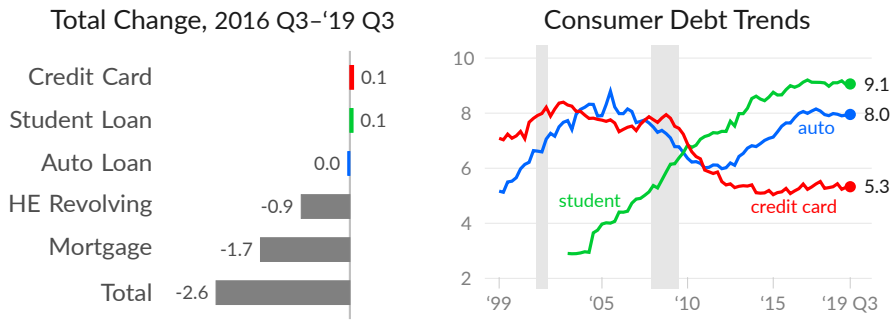
Household and Nonprofit Debt
by type, as share of disposable personal income



Source: Federal Reserve and Bureau of Economic Analysis

Federal Reserve Bank of New York (FRBNY) analysis of Equifax data shows $13.952 trillion in total consumer debt in 2019 Q3, which is equivalent to 84.4 percent of disposable personal income. Over the past three years, total consumer debt has increased by $1.60 trillion compared to an increase of $2.33 trillion in disposable personal income. As a result, the ratio of total consumer debt to disposable personal income has fallen by 2.6 percentage points over this period.

Mortgages and Consumer Credit
share of disposable personal income, percent



Source: Federal Reserve Bank of New York and Bureau of Economic Analysis

Trends in household debt over the past three years, measured in both the US Financial Accounts and the New York Fed Consumer Credit Panel, show consumer credit growing in line with income while mortgage debt falls relative to income. The two series below, Mortgage Debt Total and Consumer Credit, are comparable between both data sources. Discrepancies arise because the Financial Accounts include debt of nonprofit institutions and the Consumer Credit Panel does not include persons without a social security number.

According to the same FRBNY data, mortgage debt, including home equity lines of credit, totalled $9,833 billion in 2019 Q3, equivalent to 59.5 percent of disposable personal income (DPI). Student loans totalled $1,498 billion, or 9.1 percent of DPI; auto loans totalled $1,315 billion (8.0 percent of DPI); and credit card debt totalled $881 billion (5.3 percent of DPI).

Over the past three years, the ratio of total mortgage debt to disposable personal income fell by 2.6 percentage points, compared to an increase of 0.1 percentage points for student loans, virtually no change for auto loans, and an increase of 0.1 percentage points for credit card debt

Assets

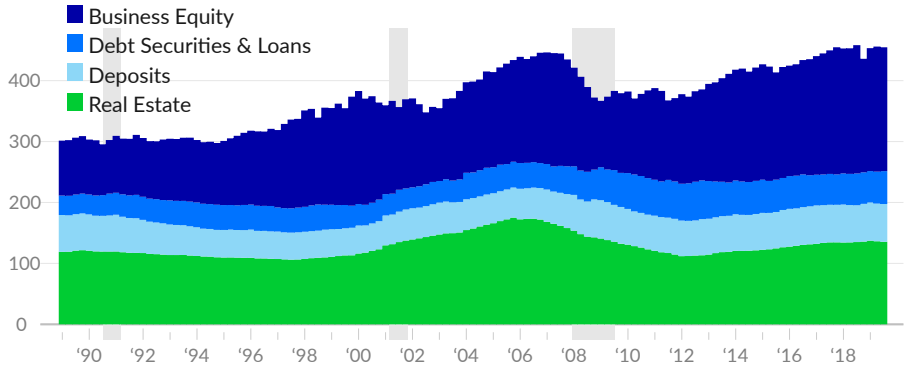
Assets of households and nonprofits were valued at $130.2 trillion in 2019 Q3, equivalent to 604 percent–or 6.04 years–of GDP. Of this, $39.2 trillion, or 30.1 percent of the total, are tangible assets and $91.0 trillion, or 69.9 percent, are financial assets.

Tangible, or non-financial, assets include peoples' homes as well as consumer durable goods, such as cars, furniture, and appliances. The market value of owner-occupied real estate is $29.2 trillion in 2019 Q3, equivalent to 1.35 years of GDP (see ■). Consumer durable goods have a replacement value of $5.7 trillion, or 0.27 years of GDP. Tangible assets are reported for the combined household and nonprofit sector and include real estate and equipment belonging to nonprofits, which totals $4.3 trillion in 2019 Q3.

Financial assets include equity in businesses–corporate and non-coporate–with a market value of $43.8 trillion, or 2.03 years of GDP (see ■), in 2019 Q3. Debt securities and loan assets total $11.6 trillion, or 0.54 years of GDP (see ■). Cash and deposits, including money market accounts, total $13.4 trillion, or 0.62 years of GDP (see ■). All other financial assets total $22.2 trillion.

Selected Household and Nonprofit Assets

share of GDP



Source: Federal Reserve, Bureau of Economic Analysis

Household and nonprofit assets grew by 1.9 percent over the year ending 2019 Q3. Owner-occupied real estate contributed 0.6 percentage points to total growth, and business equity subtracted 0.4 percentage points.

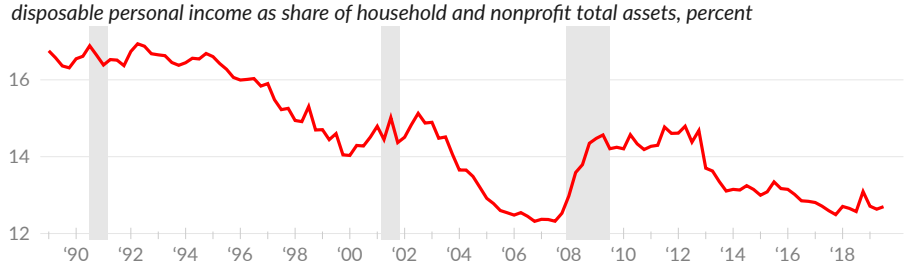
Source: Bureau of Economic Analysis

The increase in assets as a share of GDP also means that the return on total household assets has fallen, as measured by disposable income as a share of household assets. As of 2019 Q3, disposable income was equivalent to 12.7 percent of total assets, compared to an average rate of 16.0 percent during the 1990s.

Return on Household Assets

disposable personal income as share of household and nonprofit total assets, percent



Source: Federal Reserve, Bureau of Economic Analysis

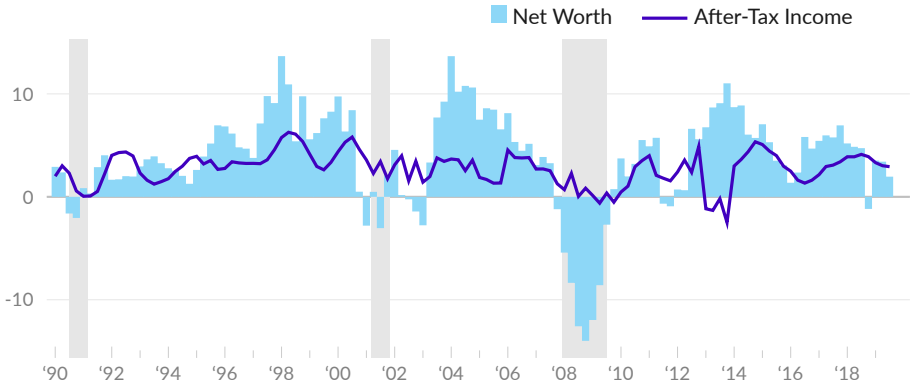
Net Worth

The total assets of households have risen much faster than their total liabilities. Net worth is an aggregate measure of the financial position of households, measured as total assets minus total liabilities. In 2019 Q3, household and nonprofit institution net worth was $113.8 trillion, equivalent to 6.9 years of disposable personal income; the result of total assets of $130.2 trillion and total liabilities of $16.4 trillion.

In 2019 Q3, inflation-adjusted net worth increased by 2.0 percent (see), while inflation adjusted after-tax income increased by 2.9 percent (see —). Over the past three years, real net worth grew at an average rate of 4.4 percent, while real after-tax income grew at an average rate of 3.0 percent

Net Worth and After-Tax Income Growth

one-year percent change in net worth and after-tax income, adjusted by PCE price deflator



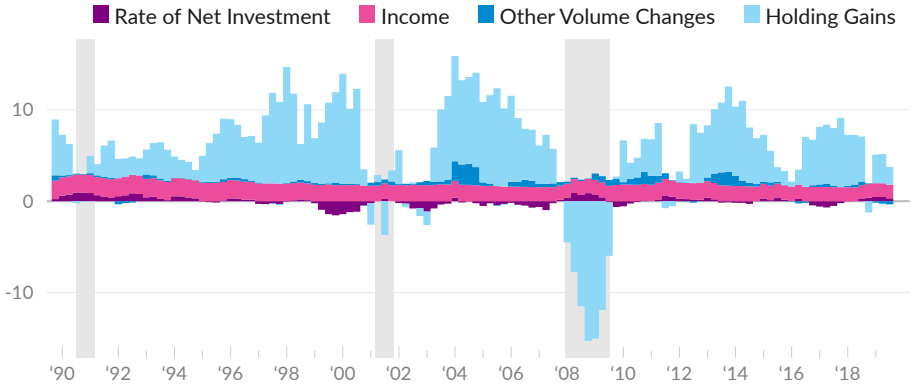
Source: Federal Reserve, Bureau of Economic Analysis

Net worth changes come from the revaluation of assets and from net investment of income. Changes to the value of assets, for example capital gains from an increase in the market value of corporate equities, explain most of the changes in net worth (see ■). Each period households also receive income and decide investment, saving, and borrowing. Net investment equals capital expenditures less depreciation plus net lending/borrowing; positive net investment results in an increase in net worth. Since 1989, household net investment has averaged 10 percent of disposable personal income. Income that goes to net investment at this historical-average rate (see ■) can be separated from periods where the rate of net investment is above or below this historical average (see ■). This distinction can identify how changes in disposable personal income, and changes in decisions about how to use that income, combine to affect net worth. Changes in data sources or from natural disasters are also identified as other volume changes (see ■).

Data are used in the following chart are not adjusted for changes in prices because it's not clear how to attribute changes in prices to holding gains, which *are* changes in prices.

Net Worth Growth

contribution to one-year percent change in net worth, nominal



Source: Federal Reserve, Bureau of Economic Analysis

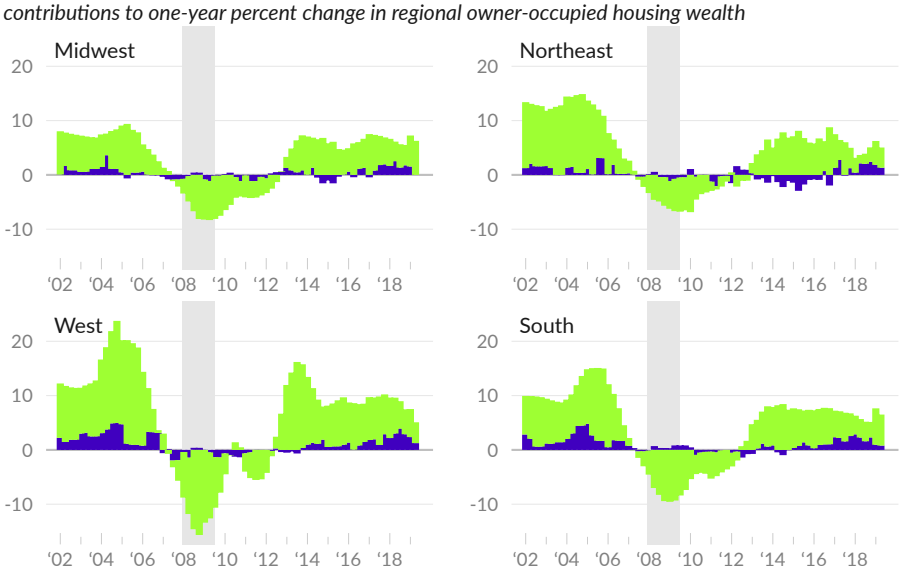
In the third quarter of 2019, holding gains contributed 1.9 percentage points to overall nominal net worth growth. Income net invested at the 1989-onward average 10.0 percent rate contributed 1.5 percentage points; and an additional 0.3 percentage points were added as household net investment was 12.2 percent of disposable person income in 2019 Q3. Other volume changes subtracted 0.3 percentage points. Over the past three years, holding gains have contributed 4.6 percentage points on average; net investment (combined) has contributed 1.8 percentage points; and other volume changes did not contribute significantly.

Housing

Some data here on the US total and regional change in the value of residential homes during and since the housing bubble.

Owner-Occupied Housing Wealth Unit Price Inventory

contributions to one-year percent change in regional owner-occupied housing wealth



Source: Federal Reserve and Census Bureau

In November 2019, 1,474,000 new residential building permits were issued, the highest level since May 2007. Permits issued increased by 13,000 (0.9 percent) over the previous month, increased by 140,000 (10.5 percent) over last November, and increased by 412,000 (38.8 percent) total over the past five years.

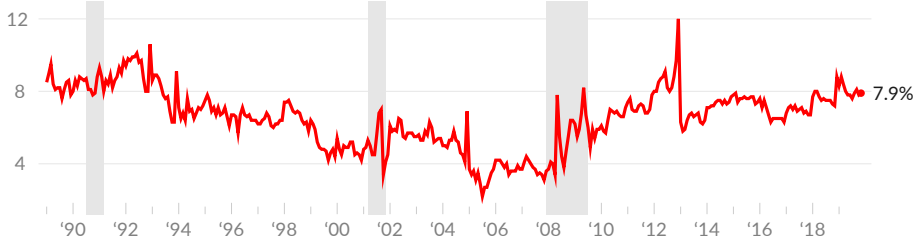
Saving

The portion of after-tax income that is not spent by households is considered personal saving, from an economic accounting perspective. Personal saving as a share of disposable personal income is referred to as the personal saving rate. Households use savings to handle unexpected expenses or cover expenses when income falls. However, economists also point out that aggregate personal saving is a direct reduction in corporate profits, as it represents income to persons that was at some point a business expense, but that does not get returned to businesses as revenue through consumer spending.

As of November 2019, the Bureau of Economic Analysis reports a rate of personal saving of 7.9 percent. Over the past three years, the personal saving rate increased by a total of 1.4 percentage points.

Personal Saving Rate

personal saving as a share of disposable personal income



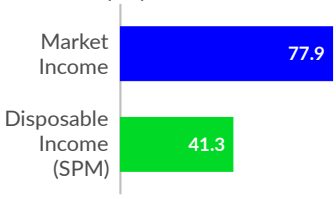
Source: Bureau of Economic Analysis

Poverty

In 2018, income from labor and capital ownership, called market income, was below the Census Bureau threshold for poverty for 77.9 million people in the US. After-tax income, or disposable income, includes income from various government programs and tax credits, such as social security and the child tax credit, and subtracts taxes paid. By disposable income, 41.3 million people are in poverty. In other words, government programs and tax credits moved the income of 36.6 million people above the poverty threshold.

In Poverty, 2018

millions of people



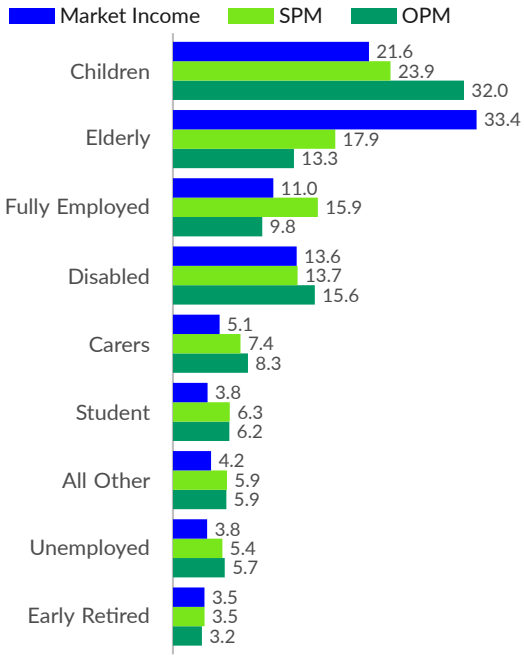
Source: CPS ASEC

The Census Bureau reports 41.2 million people in poverty in the US in 2018, equivalent to more than the total population of Canada. For purposes of program eligibility and economic data, poverty is defined by having income below a certain threshold. The processes for calculating poverty vary, with the official measure being based on three times a price-adjusted 1963 minimal food budget, and the supplemental measure based on food, shelter, clothing, and utilities costs and additionally capturing program benefits and taxes, along with other adjustments.

While some fully-employed people are in poverty, the vast majority of poor people are children, elderly, disabled, caregivers, and students. That is, there is often a good reason why poor people are not working. Put another way, if the missing labor income required to keep a person out of poverty is not supplied in the form of capital income or welfare income, the person will be poor.

In Poverty Population by Category

share of total, 2018

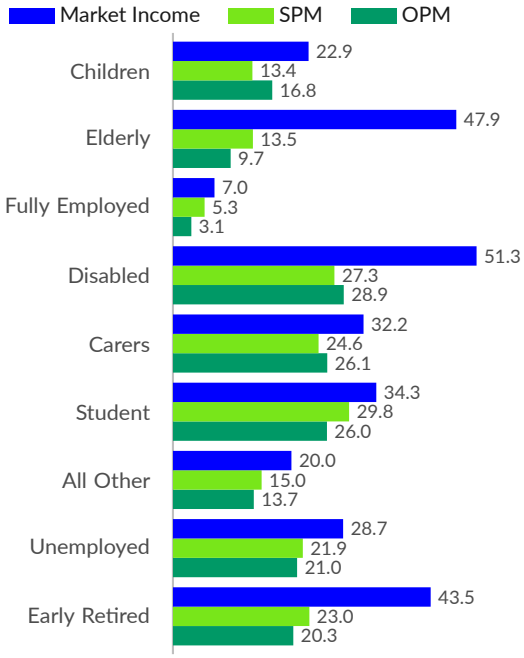


Source: CPS ASEC

The share of a group whose combined labor, capital, and welfare income is below the poverty line is the poverty rate for the group. In 2018, students, caregivers, and the disabled had the highest rates of poverty. Those fully-employed have a very low rate of poverty. The elderly also have a much lower poverty rate as the result of Social Security.

Poverty Rate by Category

share of group below poverty line, 2018



Source: CPS ASEC

By age, market income leaves the elderly particularly vulnerable, given higher average expenditure on healthcare. After welfare income and taxes, the elderly have much lower rates of poverty. After-tax income leaves students and below social security and medicare age vulnerable.

Businesses

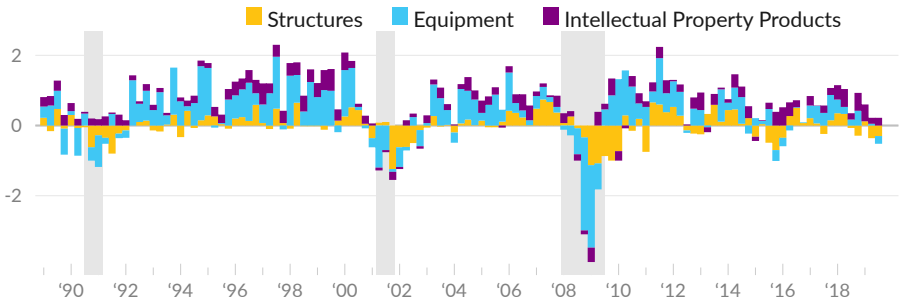
The factories, offices, and equipment that workers use to produce goods and services are all important to the economy. This section looks at the loosely defined business sector, with data covering business investment, retail sales, industrial production, corporate profits, and the financial activities of businesses.

Fixed Investment

When businesses purchase items with a useful life of more than one year it is considered and investment in fixed assets, which is an exchange of assets rather than an expense. Investments in fixed assets that make workers more productive, by definition, allow businesses to produce goods and services using less effort from people. Business gross investments in fixed assets are grouped broadly as structures (see), equipment (see), and intellectual property products (see).

Business Fixed Investment

percentage point contribution to GDP growth



Source: Bureau of Economic Analysis

Business investment subtracted 0.31 percentage points from GDP growth in the third quarter of 2019 compared to an average contribution of 0.53 percentage points over the past three years. In 2019 Q3, investment in structures subtracted 0.30 percentage points from GDP growth, investment in equipment subtracted 0.22 percentage points, and investment in intellectual property products contributed 0.22 percentage points.

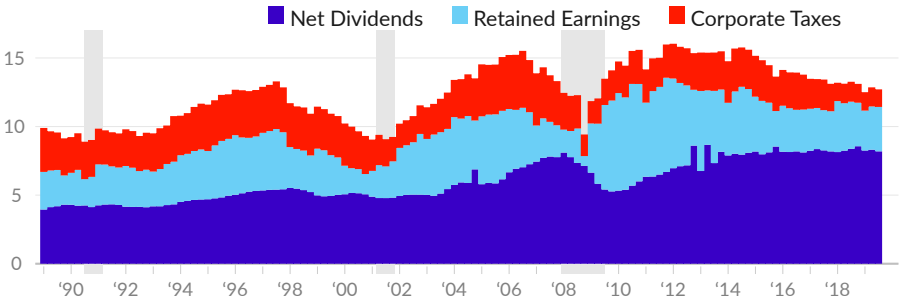
Corporate Profits

The national accounts include detailed information on aggregate corporate profits, which are an important determinant in the business cycle. In the third quarter of 2019, aggregate corporate profits were $2.08 trillion, or 12.7 percent of net national income. Of this, $1.34 trillion, equivalent to 8.2 percent of net national product, were paid out as dividends (see ■), $529 billion were retained (see ■), and $209 billion went to corporate income tax (see ■).

Destination of Corporate Profits

share of net national income



Source: Bureau of Economic Analysis

Aggregate corporate savings (corporate profits less dividends and corporate profit tax) are the result of net investment and non-business saving. Investment is a source of aggregate profit because it is revenue for one party but not an expense for the other. Non-business saving, which includes household, government, and rest of world saving, necessarily reduces aggregate corporate profits because it is money that did not return to businesses as revenue.

Sources of Corporate Saving

contribution to corporate saving, as share of gross national income

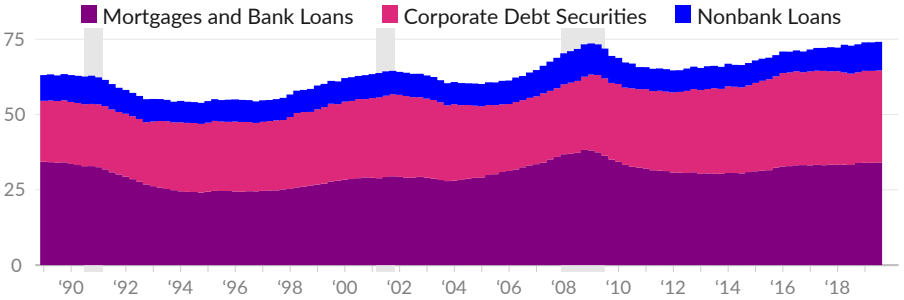
Business Debt

As of 2019 Q3, nonfinancial business debt–the debt security and loan liabilities of nonfinancial businesses–both corporate and non-corporate–totals $15,970 billion, with $10,105 billion (63.3%) held by corporate businesses. Over the past three years, nonfinancial business debt has increased faster than overall economic activity. As a share of GDP, nonfinancial business debt increased by 2.8 percentage points to 74.1 percent in 2019 Q3 from 71.3 percent in 2016 Q3. The vast majority of the increase, 2.6 percentage points, comes from nonbank loans (see ■).

Nonfinancial Business Debt

by type, as share of GDP



Source: Federal Reserve and Bureau of Economic Analysis

The debt of the domestic financial sector includes agency and government-sponsored enterprise (GSE) backed securities (see ■), corporate and foreign bonds, loans (see ■), and open market paper. The long-term increase in financial sector debt reflects the emergence and growth of various asset-backed securities. In addition to home mortgage-backed securities, the domestic financial sector issues debt securities based on commercial mortgages, auto loans, credit card, student debt, and even restaurant revenue.

Domestic financial sector debt has fallen as a share of GDP to 77.0 percent in 2019 Q3 from a housing-bubble peak of 124.3 percent in 2009 Q1.

Industrial Production

Manufacturing production increased at an annual rate of 1.3 percent over the past three years, as of November 2019, but remains 4.7 percent below its December 2007 rate. Total industrial production increased at an annual rate of 2.4 percent over the same period. Mining production increased at an annual rate of 8.9 percent, while production of electric and gas utilities increased at an annual rate of 2.4 percent.

By market group, production of consumer goods increased at an annual rate of 1.0 percent over the past three years, as of November 2019. Production of business equipment increased at an annual rate of 3.2 percent, production of nonindustrial supplies increased at an annual rate of 1.1 percent, and production of materials increased at an annual rate of 3.5 percent.

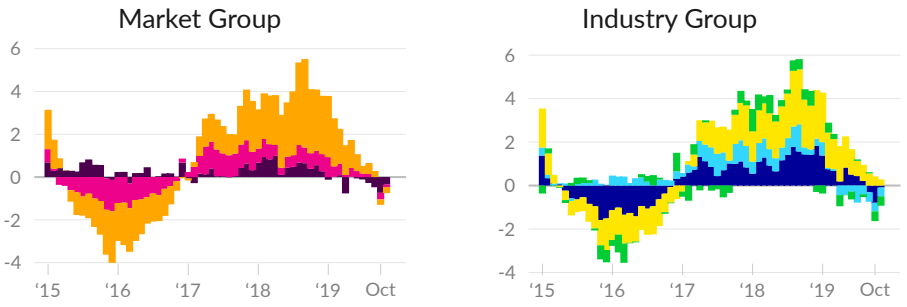
The most recent slowdown has been broad-based. The monthly data are shown in detail below.

Recent data in detail



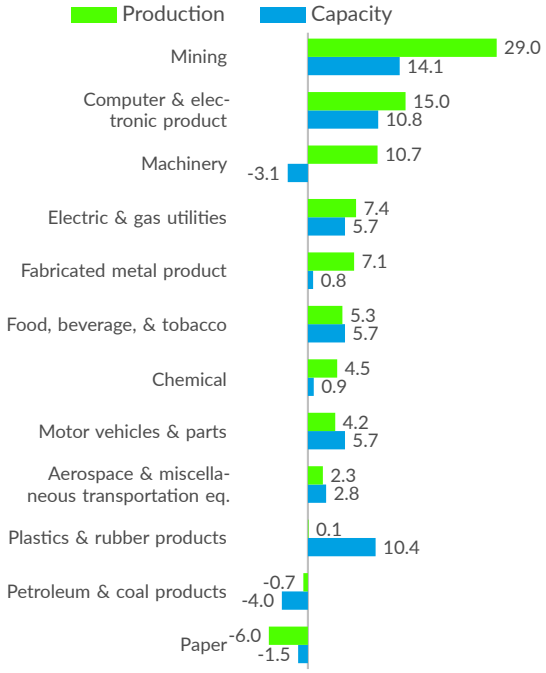
Source: Federal Reserve

Of a subset of 12 industries that contribute the majority of industrial production, nine increased production over the past three years, two decreased production, and one was unchanged. Mining production increased by 29.0 percent in total over the three years ending November 2019. Computer & electronic product production increased by 15.0 percent, and machinery production increased by 10.7 percent. In contrast, paper production decreased by 6.0 percent over the same period.

Over the three years ending November 2019, nine of the 12 industries increased industrial capacity, three decreased capacity, and none were unchanged. The most significant change over the period was an increase of 14.1 percent in mining capacity, follwed by an increase of 10.8 percent in computer & electronic product capacity.

Industrial Production and Capacity

total three-year growth, percent



Source: Federal Reserve

The Federal Reserve's monthly industrial production report also measures the economy's total industrial capacity. The extent to which the economy is using its industrial capacity is called capacity utilization, and calculated as industrial production as a share of total industrial capacity. In October 2019, the industrial capacity utilization rate was 76.7 percent, and the manufacturing capacity utilization rate was 74.7 percent.

Capacity Utilization

industrial production as a share of total capacity, percent

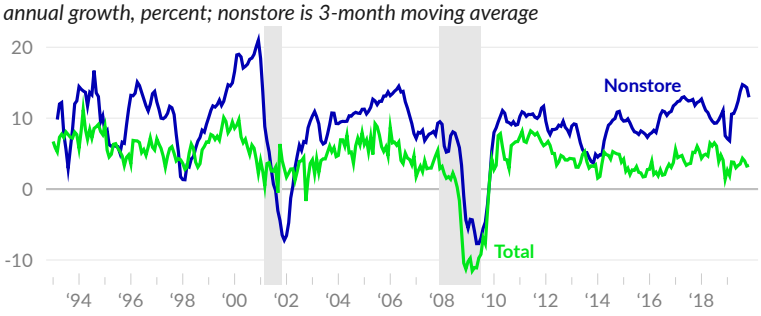
Retail Sales

According to the Census Bureau, retail and food service sales totalled $528.0 billion in November 2019, equivalent to roughly 29.4 percent of GDP on an annualized basis. Over the past year, retail and food service sales increased by 3.3 percent, without adjusting for prices. Nonstore sales, which include online retailers, have increased by 11.5 percent over the same period, and total $68.1 billion, or roughly 3.8 percent of GDP.

Retail Sales and Food Services

annual growth, percent; nonstore is 3-month moving average



Source: Census Bureau

More text here that mentions the most significant changes in retail sales. Part of the story is the overall decline, which continues in recent data. Part of the "shift to services" is just paying more of health care and education and having a larger financial system relative to other activities.

Government

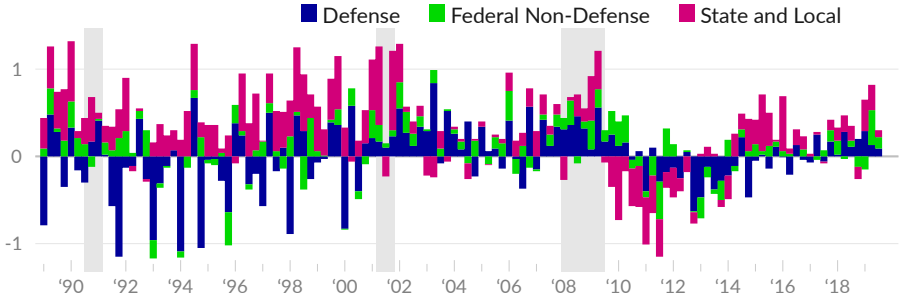
Public institutions are collectively referred to as the public-sector or the government. In the United States, the government has the authority to spend, tax, and create money, as well as to regulate private sector activities. The government also enforces policies that determine the ownership of property. These activities are all extremely important in determining production and distribution in the economy.

Government Spending and Investment

Government consumption expeditures and gross investment, which provide services and infrastructure, contributed 0.3 percentage points to real GDP growth in 2019 Q3, compared to an average contribution of 0.39 percentage points over the past year and an average of 0.23 percentage points since 1989. In 2019 Q3, federal defense (see ■) contributed 0.09 percentage points, federal nondefense (see ■) contributed 0.13 percentage points, and state and local government (see ■) contributed 0.08 percentage points.

Government Consumption and Investment

percentage point contribution to GDP growth



Source: Bureau of Economic Analysis

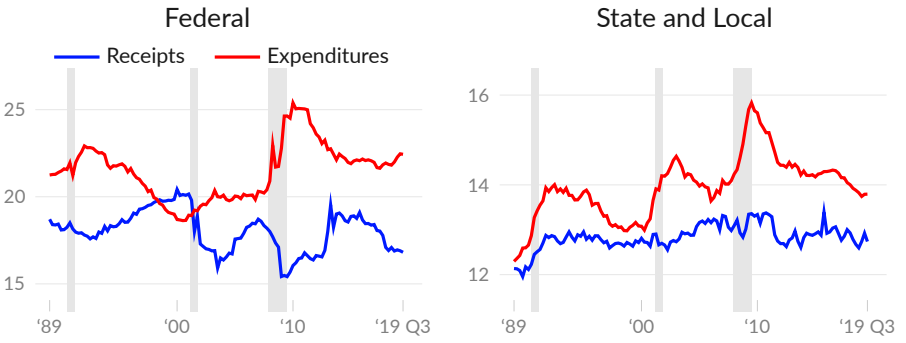
[Table here.]

Government expenditures provide services and income to people. Government receipts remove demand from the economy. When government expenditures exceed receipts, it is referred to as a government deficit, and corresponds to a private sector surplus. The size of the government deficit relative to GDP gives insight into the extent to which the government is stimulating the economy by increasing household income and corporate profits.

In 2019 Q3, federal government expenditures total $4.8 trillion, equivalent to 22.4 percent of GDP, and receipts total $3.6 trillion, or 16.8 percent of GDP. The federal deficit was therefore $1.2 trillion or 5.6 percent of GDP. Over the past three years, the ratio of expenditures to GDP increased by a total of 0.3 percentage points, and the ratio of receipts to GDP has decreased by a total of 1.7 percentage points, causing the deficit to widen by 2.0 percent of GDP.

Consolidated state and local government expenditures total $3.0 trillion, or 13.8 percent of GDP, in 2019 Q3, and receipts total $2.7 trillion, equivalent to 12.7 percent of GDP. The combined state and local government deficit was $227 billion or 1.06 percent of GDP. Over the past three years, the expenditures to GDP ratio decreased by a total of 0.54 percentage points at the consolidated state and local level, and the ratio of receipts to GDP has decreased by a total of 0.30 percentage points, causing the deficit to shrink by 0.24 percent of GDP.

Receipts and Expenditures as Share of GDP

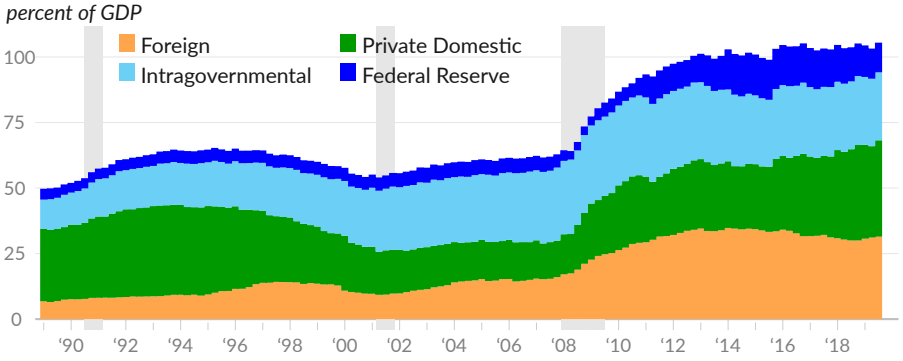


Source: Bureau of Economic Analysis

In the third quarter of 2019, total public debt was $22.7 trllion, equivalent to 105.5 percent of GDP. Of this, $7.9 trillion, or 34.9 percent of the total, is held by private domestic investors (see ■). An additional $6.8 trillion, or 29.8 percent of the total, is held by foreign investors (see ■). The remainder is held by the Federal Reserve (see ■) and various government agencies and trusts (see ■), such as the Social Security Trust Fund.

Total Public Debt By Holder

percent of GDP



Source: Treasury

The ratio of public debt to GDP is fairly stable, and the interest income from holding public debt is lower than in the past because of lower interest rates. Treasuries and other government debt securities provide a stable asset for the balance sheets domestic households and businesses, and for foreign investors.

International Transactions

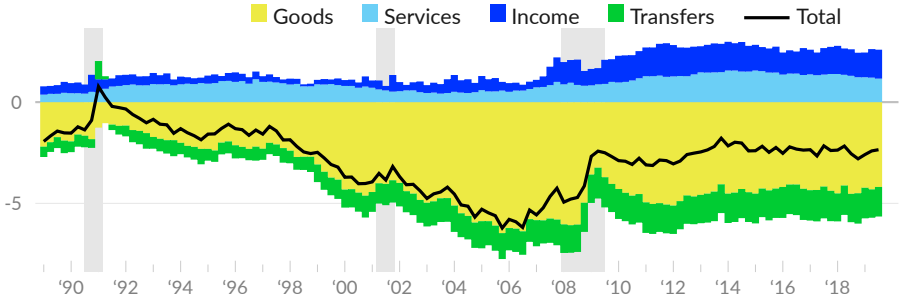
Transactions between the US and the rest of the world are recorded in the balance of payments as either current account transactions (which measure income) or capital and financial account transactions (which measure change in ownership of assets). This section details imbalances in international transactions, changes in trade by goods and by partner, international investment positions, and exchange rates.

Balance of Payments

The current account balance can be decomposed into the balance on trade in goods (see), the balance on trade in services (see), the balance on primary income (such as wages or income from assets, referred to here as income [see]), and secondary income (such as remittances and taxes, referred to here as transfers [see]). As of 2019 Q3, the US runs a current account deficit of 2.4 percent of GDP, primarily as the result of a trade deficit on goods of 4.2 percent of GDP.

Current Account Balance

balance on individual current account component, as percent of GDP



Source: Bureau of Economic Analysis

Financial account transactions include the net domestic acquisition of foreign assets and the net domestic incurrence of foreign liabilities. The US financial account balance (see) is the net lending or borrowing of the combined domestic sectors with the rest of the world. The timing of payments lead to a statistical discrepancy (see), but the financial and capital account balance and current account balance otherwise sum to zero.

Over the year ending 2019 Q3, net domestic acquisitions of foreign assets were equivalent to 2.4 percent of GDP, while net domestic incurrence of foreign liabilities total 4.3 percent of GDP. Domestic net borrowing totals 1.9 percent of GDP.

Financial Account Balance

percent of GDP

[Capital account balance chart]

[TABLE similar to ITA table 1.1]

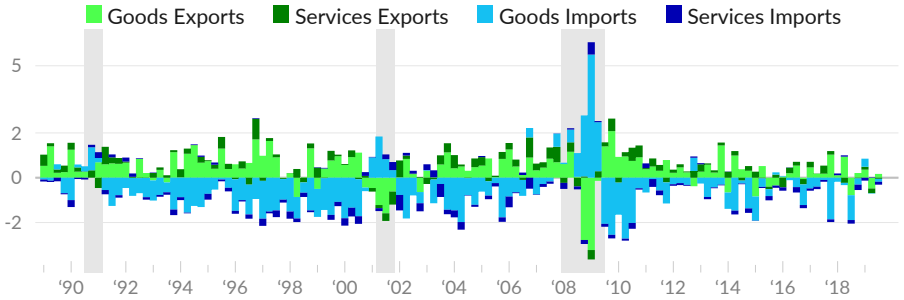
Trade

The trade balance (exports of goods ■ and services ■ minus imports of goods ■ and services ■) acts as an adjustment to consumption and investment in GDP calculations. As the US runs a persistent trade deficit, trade will generally subtract from GDP growth. In the income approach, the expanded trade deficit reduced nominal compensation of employees (extensive margin through outsourcing, intensive margin through lower wages from labor market slack) and reduced prices.

Goods exports contributed 0.17 percentage points to GDP growth in the third quarter of 2019 while services exports subtracted 0.05 percentage points. Good imports subtracted 0.13 percentage points from GDP growth and services imports subtracted 0.13 percentage points.

International Trade

percentage point contribution to GDP growth

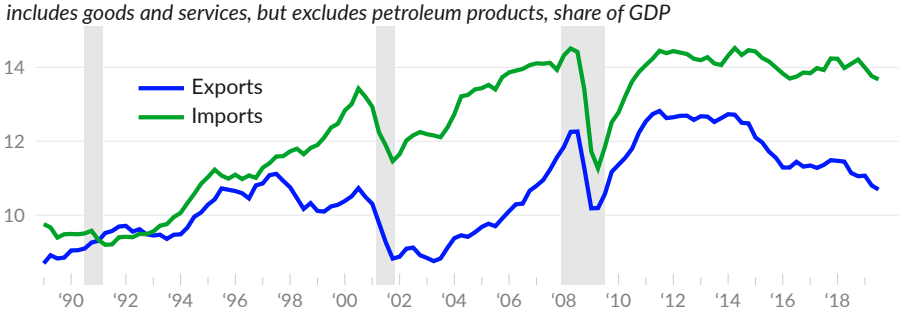


Source: Bureau of Economic Analysis

Nonpetroleum goods and services imports (see —) were equivalent to 13.7 percent of GDP in the third quarter of 2019, while exports of nonpetroleum goods and services (see —) were equivalent to 10.7 percent of GDP.

Imports and Exports, Nonpetroleum

includes goods and services, but excludes petroleum products, share of GDP



Source: Bureau of Economic Analysis

Changes to the trade balance come from a myriad of potential sources, such as changes in demand or relative supply of other countries, changes in exchange rates, changes in preferences for categories of goods, changes in trade policy, and changes in domestic demand. The following table captures the nominal value of major categories of goods and services as a share of nominal gross domestic product at various points over the past 30 years.

Goods can be produced domestically or imported or some combination of the two. The import share of the total US demand for goods, measured as US produced goods and imported goods less exported goods, is also referred to as “import penetration”. This measure has risen considerably over the past thirty years. The majority of the long-term increase has been concentrated in consumer goods, while the decrease since 2011 has come primarily from petroleum and products.

From 1989 to 2011, imports of consumer goods increased by the equivalent of 6.0 percent of domestic consumption of goods (see); petroleum and products imports increased by the equilavent of 6.1 percent (see); and all other goods, primarily capital good, industrial supplies, and materials, increased by the equivalent of 6.2 percent (see). Since 2011, imports of consumer goods increased by the equivalent of 0.2 percent of domestic goods demand; imports of petroleum and products decreased by the equivalent of 5.6 percent; and other imports decreased by the equivalent of 0.8 percent.

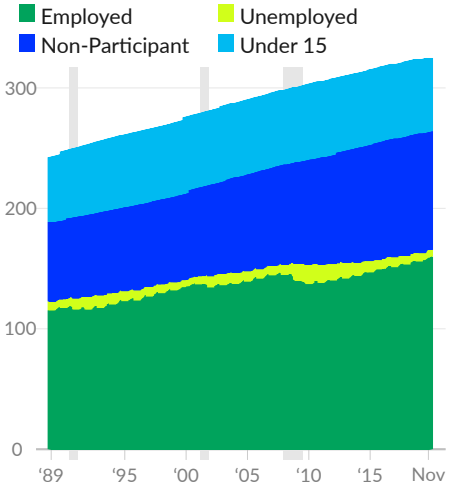
Labor Markets

Labor is the primary source of income for US households and is essential to the production of goods and services. The portion of labor that is provided by a household member to others outside of the household or to other households is called employment. As of November 2019, 159.9 million people are employed (including self-employment).

Labor provided within a household is not captured by GDP compilation methods (expenditures, output, or income), though household surveys offer some insight into this important category of labor. The number of people who are considered employed divided by the total population is the employment rate or employment-to-population ratio, which is 49.2 percent as of November 2019.

Labor Force Status of Population

millions of people



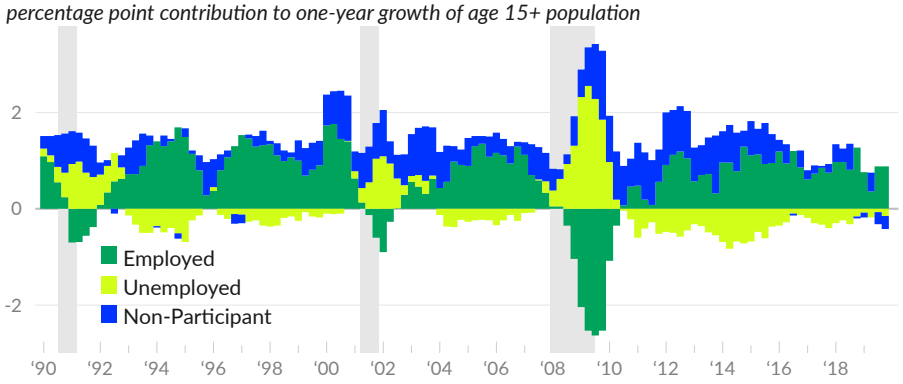
Source: Author's Calculations from CPS

When a member of a household is not employed but looked for a job during the past four weeks and is available to work, they are considered unemployed. As of November 2019, there are 5.5 million unemployed people. The combined group of employed and unemployed people is the labor force. The number of unemployed people divided by the number of people in the labor force is the unemployment rate, currently 3.3 percent. The number of people in the labor force divided by the total population is the labor force participation rate, currently 50.9 percent.

People who are not employed and not unemployed are considered to be outside of the labor force. This category is about half of the population, on average, and totals 98.7 million in November 2019. The category is comprised of children (60.7 million), students (18.5 million), unpaid caregivers (12.2 million), those unable to work due to disability or illness (14.2 million), those who want a job but have given up looking (4.1 million), and retirees and the elderly (47.3 million).

Labor Force Status Changes

percentage point contribution to one-year growth of age 15+ population



Source: Author's Calculations from CPS

The labor force status of the US population varies by age, sex, and over time. Because very few people have capital income, the share of the population with labor income is particularly important to overall levels of economic activity.

Labor Force Status

November 2019, thousands of people, not seasonally adjusted

	Total, 15+	Men, 15–29	Men, 30–59	Men, 60+	Women, 15–29	Women, 30–59	Women, 60+
Population	264,183	32,547	61,358	33,998	32,228	63,687	40,365
Employed	159,930	19,381	52,609	12,269	18,476	46,692	10,503

Retirement	47,145	104	1,402	18,308	184	1,995	25,153

Source: Author's Calculations from CPS

Additionally, changes over time in labor force status are particularly important to understanding both secular and cyclical trends in the economy. For example, the US population is growing but it is also aging. Over the past year, there was a substantial shift towards full-time work.

Gross Labor Income

In labor markets, unlike other markets, wages (the price of labor) tend not to be cut in response to a decrease in demand; businesses instead employ fewer workers and/or cut hours. As a result, wage data give only a partial picture of the labor income received by households.

Gross labor income (compensation of employees in the national accounts), which captures both employment and wages, increased at an annualized and inflation-adjusted rate of 2.12 percent in 2019 Q3. Changes in wages subtracted 1.14 percentage points, and changes in total hours worked contributed 3.26 percentage points.

Gross Labor Income Growth

percentage point contribution to gross labor income growth

Employment

In December 2019, 80.4% of 25-54 years olds were employed, the highest level since July 2001. Over the past year, the age 25-54 employment rate has increased by 0.8 percentage points. The current age 25-54 employment rate is 0.9 percentage points (equivalent to 1.1 million workers) below the average during 1998–99, a period with a particularly tight labor market.

Employment Rate

employed share of age 25-54 population

Source: American Community Survey

The monthly establishment survey enables tracking of non-farm payrolls. In September 2019, the US economy added 136,000 jobs. In 2019 Q2, the US added an average of 146,000 jobs per month, compared to 205,000 in 2019 Q1 and an annual average of 205,000 in 2018.

[Quarterly employment growth with dot for latest monthly value]

Employment rates vary over time, but also by age, gender, and education. Over the 12 months ending November 2019, the employment rate for most education groups is lower than it was on average in the year 2000. Only older workers and women with advanced education have higher rates of employment than in 2000. Fix text...

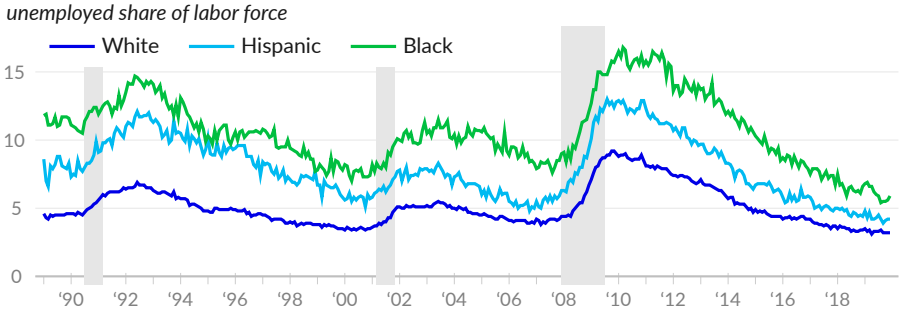
Unemployment

The conventional "unemployment rate" is measured as the number of people who do not have a job and looked for one during a reference week, divided by the labor force, which includes the unemployed and those with jobs.

Unemployment is currently very low. BLS reports 5.8 million unemployed persons in December 2019, and an unemployment rate of 3.5 percent. However, unemployment is much higher for disadvantaged groups, with the black or African American unemployment rate typically double the white unemployment rate. A very tight labor market may have the effect of reducing racial discrimination in hiring. Over the past year, the black or African American unemployment rate has fallen by 0.7 percentage points to 5.9 percent.

Unemployment Rate

unemployed share of labor force



Source: Bureau of Labor Statistics

Reasons for unemployment

There are multiple reasons for unemployment. During the trough of a business cycle, most unemployed are those who lost a job, for example from layoffs, or had a temporary job end (see ■). In general, many of the unemployed are re-entrants to the labor market, meaning they were out of the labor force prior but are looking for a job again (see ■). Some are new-entrants who are looking for their first job (see ■). A small portion are also those who left a job voluntarily and are looking for a new one (see ■).

In December 2019, 1.6 percent of the labor force were unemployed because of losing a job or having a job end, 0.5 percent were re-entrants, 1.0 percent new entrants, and 0.3 percent job leavers.

Unemployment by Reason

unemployed share of labor force, by reason for unemployment

Unemployment by duration

Summary text about local area estimates of unemployment. Will need to think about tables that show highlights, because there are too many MSAs to list all data. Something that captures diffusion would be nice. Perhaps I can list how many metro areas had the unemployment rate fall over the past year, and then talk about how many unemployed people that actually means–so that population is taken into consideration in some meaningful way.

Change in Unemployment Rate by Metro Area

Non-participation

Start with chart of labor force participation rate, including age-adjusted version. Alternatively, tie the size of unemployment to the size of non-participation. The things I want to capture in this section:

1) Definitions

2) Long-term trend–increase in female participation

3) Aging population puts downward pressure

4) Reasons for non-participation

5) Disability as a reason

6) School as a reason

7) Retirement as a reason

8) Care for family – elder care

9) Care for family – child care

10) Recent trends

11) At least one good crosstab

12) Geographic specificity if possible

The Current Population Survey asks people who are not employed or looking for work about their major activities and reasons for not participating in the labor market. The answers show a tendency to vary by age, in intuitive ways, but also a strong relationship to the business cycle. By age, those age 16–24 who are not in the labor force disproportionately cite school as the reason for non-participation, while those 55+ disproportionately cite retirement.

[CHART HERE – bar chart]

An important contribution to ..

Of those age 18–64, the majority are employed (XX.X percent), as of October 2019, and very few are unemployed (X.X percent of the age group). An additional XX.X percent are not in the labor force.

While the recession of 2001 appears mild in measures of expenditure, it was followed by a substantial reduction in the share of the population earning labor income. The economy was still losing jobs at an alarming rate long after the 2001 recession had officially ended, with some overall weakness masked by a major housing bubble. The burst of the housing bubble caused the great recession seven years after, pushing many more people out of the labor force. From March 2001 to the latest available month, October 2019, an additional X.X percent of the age 18–64 population left the labor force. The larger-than-normal population cohort born after World War II reached retirement age in this period, such age and sex-related effects explains X.X percent of the cumulative decrease. Additionally, young people are staying in school longer, on average, reducing the age 18–64 labor force by X.X percent. Disability or illness reduced the labor force by another X.X percent. Less retirement among those age 18–64 increased the labor force by X.X percent..

Contributions to Labor Force Participation Since March 2001

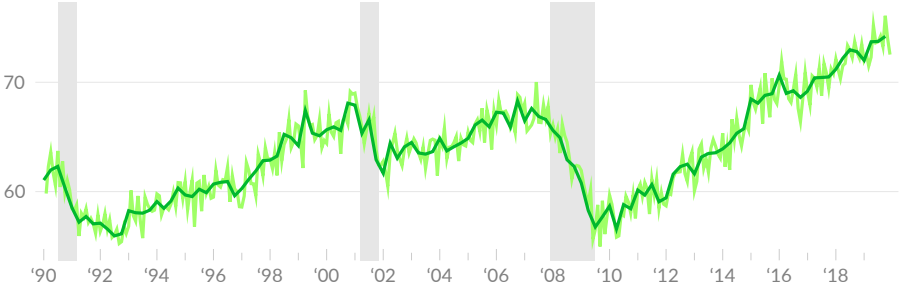
Labor Force Flows

Among newly employed workers, the vast majority were considered to be out of the labor force the prior month, as opposed unemployed. In December 2019, 6.4 million people were newly employed (on a gross basis). Of these, 72.5 percent were not looking for work in the prior month. With low unemployment, new employees are being pulled from outside of the labor force and bypassing unemployment. Three years ago, in December 2016, 70.9 percent of the newly employed were not looking for work month prior.

Newly Employed, Not Previously Looking For Work

share of newly employed that were not looking for work in the prior month



Source: Bureau of Labor Statistics

The great recession worsened job-finding prospects for those not in the labor force (NILF) due to disability or illness. Only over the past few years have these prospects recovered. Over the year ending November 2019, 8.5 percent of persons age 25–54 who were NILF due to disability in the prior year are now employed. This one-year rate of job-finding has increased substantially from its 2010–2013 average of 6.0 percent

Job growth

Wage growth:

[AHE and UWE both in various forms]

[Either FRB Atlanta Wage Tracker or replication]

Wage Growth

The usual wages of full-time workers can be measured at various points in the income distribution using the Current Population Survey. BLS reports these data by decile and quartile, with the most commonly used measure being the median usual weekly earnings. The first decile usual weekly earnings of full-time workers have increased rapidly over the past year, suggesting fewer people are working full-time for less than $10 per hour.

Some types of turnover in the labor market are healthy and mean people are better able find a new job if they do not like the one they have. The Bureau of Labor Statistics reports the number of job openings, hires, and separations in several industry groups on a monthly basis. Within separations, these data distinguish voluntarily leaving of a job as "quits".

In October 2019, there were 7.3 million total job openings and 5.8 million hires completed. In the same month there were 5.6 million total separations, of which 3.5 million were voluntary. In comparison, there are 5.9 million unemployed persons in October 2019. The ratio of job openings to unemployed persons was 1.2 in the latest month, compared to 0.7 in the same month three years prior.

State- and sub-state-level analysis

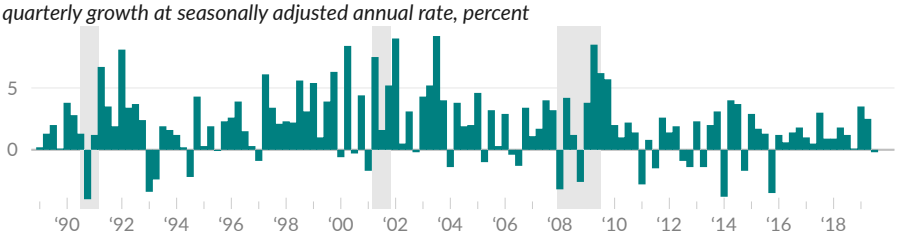
Labor Productivity

Labor productivity is reported by the Bureau of Labor Statistics and measured as real output per hour of work in the nonfarm business sector. Economic theory suggests that labor productivity is particularly important for long-term real economic growth. The measure captures the rate at which people, with all of the resources and equipment and infrastructure available to them, are able to produce goods and services with their work. An increase in labor productivity means real wages can increase without putting upward pressure on inflation. Alternatively, an increase in productivity means a society can meet its material needs with less work.

In 2019 Q3, labor productivity decreased at an annual rate of 0.2 percent (see ■), as the result of an increase of 2.3 percent in real ouput and an increase of 2.5 percent in hours worked. In the prior quarter, 2019 Q2, labor productivity increased at an annual rate of 2.5 percent, as real output increased at an annual rate of 1.9 percent and hours of work decreased at an annual rate of 0.2 percent. Over the past five years, labor productivity growth has averaged 1.0 percent, compared to a 1989-onward average of 2.0 percent.

Labor Productivity Growth

quarterly growth at seasonally adjusted annual rate, percent



Source: Bureau of Labor Statistics

There are two areas to investigate in understanding trends in productivity growth rates. The first is the theory that the level of business net investment in equipment and other capital goods, particularly relative to the size of the workforce, determines productivity growth. Such investment allows more goods and services to be produced by the same number amount of work. The second theory, sometimes called the Kaldor-Verdoorn Law, is that overall economic growth and capacity utilization determine productivity growth. In this scenario, an economy facing real resource constraints is more likely to find ways to produce goods and services more efficiently.

Union Membership

Membership in unions and employee associations has diminished in the United States over the past fifty years. Unionized jobs typically offer higher wages and better benefits and union membership tends to increase wages and benefits even in nonunion jobs. Therefore, some research argues, less union membership increases income inequality.

Over the 12 months ending November 2019, the share of jobs held by union and employee association members averaged 10.3 percent. In levels, there were 14.6 million union jobs, and 127.0 million nonunion jobs, on average over the period. This union membership rate averaged 10.5 percent during the 12 months ending November 2018, and 10.8 percent during the 12 months ending November 2017. Union jobs decreased by 146,000 from November 2018 to November 2019, while nonunion jobs increased by 1,868,000.

Interest Rates

The US Federal Reserve System (Fed) has a congressional mandate to promote price stability and maximum employment. In practice, a Fed committee determines the federal funds rate, which aims to influence interest rates in the broader economy. Fed monetary policy can be neutral or be used to stimulate or slow the economy.

Actual data here on recent moves by the Fed and the Fed funds rate.

Money and Monetary Policy

The Federal Reserve reports the weekly average money stock, broadly, as M2, which includes cash and deposits such as savings accounts and checking accounts. In the week of December 30, 2019, the M2 measure of money averaged $15.5 trillion, equivalent to 72.1 percent of GDP. Institution money market accounts, which are not included in M2, can be combined with M2 to create a slightly-broader-than-M2 measure of the money stock. These funds averaged $2.3 trillion in the same week, equivalent to 10.6 percent of GDP.

A large increase in the amount of money held by individuals and institutions can be the result of a higher rate of saving, a larger government sector financial deficit, an increase in the money supply, a change in preferences for liquidity, or something else. In December 2019, the M2 plus institutional money funds measure increased over the equivalent previous year value by 8.8 percent.
